Exercise 1

(a)

Define

$$y := x^T W - b^T$$

$$\begin{aligned} p_\theta(x) &= \sum_{h \in \{-1,0,1\}^N} p(x, h) \\ &= \sum_{h \in \{-1,0,1\}^N} \frac{1}{Z} \exp(yh + x^T a) \\ &= \frac{1}{Z} \exp(x^T a) \sum_{h \in \{-1,0,1\}^N} \exp(yh) \\ &= \frac{1}{Z} \exp(x^T a) \sum_{h \in \{-1,0,1\}^N} \exp\left(\sum_{i=1}^N y_i h_i\right) \\ &= \frac{1}{Z} \exp(x^T a) \sum_{h \in \{-1,0,1\}^N} \prod_{i=1}^N \exp(y_i h_i) \end{aligned}$$

Because the expression $\exp(y_i h_i)$ only depends on the i 'th component of h , we can rewrite the sum and product to get:

$$\begin{aligned} p_\theta(x) &= \frac{1}{Z} \exp(x^T a) \prod_{i=1}^N \sum_{h \in \{-1,0,1\}} \exp(y_i h_i) \\ &= \frac{1}{Z} \exp(x^T a) \exp\left(\log\left(\prod_{i=1}^N \sum_{h \in \{-1,0,1\}} \exp(y_i h_i)\right)\right) \\ &= \frac{1}{Z} \exp(x^T a) \exp\left(\sum_{i=1}^N \log\left(\sum_{h \in \{-1,0,1\}} \exp(y_i h_i)\right)\right) \\ &= \frac{1}{Z} \exp(x^T a) \exp\left(\sum_{i=1}^N \log(1 + e^{y_i} + e^{-y_i})\right) \\ &= \frac{1}{Z} \exp(x^T a) \exp\left(\sum_{i=1}^N \log(1 + 2\cosh(y_i))\right) \\ &= \frac{1}{Z} \exp(x^T a + \sum_{i=1}^N \log(1 + 2\cosh(w_i x - b_i))) \end{aligned}$$

$$\begin{aligned}
&= \frac{1}{Z} \exp(x^T a + \sum_{i=1}^N \log(2(\frac{1}{2} + \cosh(w_i x - b_i)))) \\
&= \frac{1}{Z} \exp(x^T a + \sum_{i=1}^N \log(2) + \log(\frac{1}{2} + \cosh(w_i x - b_i))) \\
&= \frac{1}{Z} \exp(N \log(2) + x^T a + \sum_{i=1}^N \log(\frac{1}{2} + \cosh(w_i x - b_i))) \\
&= \frac{1}{Z} 2^N \exp(x^T a + \sum_{i=1}^N \log(\frac{1}{2} + \cosh(w_i x - b_i)))
\end{aligned}$$

With

$$Z' := \frac{2^N}{Z}$$

the desired result follows.

(b)

First compute gradients of F :

$$\begin{aligned}
\nabla_{a_i} F(x) &= \nabla_{a_i} - a^T x = -x_i \\
\nabla_{b_j} F(x) &= - \sum_{k=1}^N \nabla_{b_j} \log(\frac{1}{2} + \cosh(w_k x - b_k)) \\
&= - \nabla_{b_j} \log(\frac{1}{2} + \cosh(w_j x - b_j)) \\
&= - \frac{1}{\frac{1}{2} + \cosh(w_j x - b_j)} \nabla_{b_j} \cosh(w_j x - b_j) \\
&= - \frac{1}{\frac{1}{2} + \cosh(w_j x - b_j)} \sinh(w_j x - b_j) \nabla_{b_j} b_j \\
&= - \frac{\sinh(w_j x - b_j)}{\frac{1}{2} + \cosh(w_j x - b_j)} \\
\nabla_{w_{ij}} F(x) &= - \sum_{k=1}^N \nabla_{w_{ij}} \log(\frac{1}{2} + \cosh(w_k x - b_k)) \\
&= - \nabla_{w_{ij}} \log(\frac{1}{2} + \cosh(w_j x - b_j)) \\
&= - \frac{\sinh(w_j x - b_j)}{\frac{1}{2} + \cosh(w_j x - b_j)} \nabla_{w_{ij}} (w_j^T x) \\
&= - \frac{\sinh(w_j x - b_j)}{\frac{1}{2} + \cosh(w_j x - b_j)} x_i
\end{aligned}$$

Now we can plug the gradients into the expectations:

To compute the expectations with respect to the empirical distribution, we consider observed data points $x^{(1)}, \dots, x^{(n)}$

$$\begin{aligned}
\nabla_{a_i} KL(\hat{p} || p_\theta) &= \langle -x_i \rangle_{\hat{p}} - \langle -x_i \rangle_{p_\theta} \\
&= \sum_{x \in \{0,1\}^d} x_i p_\theta(x) - \langle x_i \rangle_{\hat{p}} \\
&= \sum_{x \in \{0,1\}^d} x_i p_\theta(x) - \frac{1}{n} \sum_{k=1}^n x_i^{(k)} \\
&= \frac{1}{Z'} \sum_{x \in \{0,1\}^d} x_i \exp(-F_\theta(x)) - \frac{1}{n} \sum_{k=1}^n x_i^{(k)}
\end{aligned}$$

$$\begin{aligned}\nabla_{b_j} KL(\hat{p}||p_\theta) &= \langle -\frac{\sinh(w_j x - b_j)}{\frac{1}{2} + \cosh(w_k x - b_k)} \rangle_{\hat{p}} - \langle -\frac{\sinh(w_j x - b_j)}{\frac{1}{2} + \cosh(w_k x - b_k)} \rangle_{p_\theta} \\ &= \frac{1}{Z'} \sum_{x \in \{0,1\}^d} \frac{\sinh(w_j x - b_j)}{\frac{1}{2} + \cosh(w_k x - b_k)} \exp(-F_\theta(x)) - \frac{1}{n} \sum_{k=1}^n \frac{\sinh(w_j x^{(k)} - b_j)}{\frac{1}{2} + \cosh(w_k x^{(k)} - b_k)}\end{aligned}$$

$$\begin{aligned}\nabla_{w_{ij}} KL(\hat{p}||p_\theta) &= \langle -\frac{\sinh(w_j x - b_j)}{\frac{1}{2} + \cosh(w_k x - b_k)} x_i \rangle_{\hat{p}} - \langle -\frac{\sinh(w_j x - b_j)}{\frac{1}{2} + \cosh(w_k x - b_k)} x_i \rangle_{p_\theta} \\ &= \frac{1}{Z'} \sum_{x \in \{0,1\}^d} \frac{\sinh(w_j x - b_j)}{\frac{1}{2} + \cosh(w_k x - b_k)} x_i \exp(-F_\theta(x)) - \frac{1}{n} \sum_{k=1}^n \frac{\sinh(w_j x^{(k)} - b_j)}{\frac{1}{2} + \cosh(w_k x^{(k)} - b_k)} x_i^{(k)}\end{aligned}$$

(c)

The independence model is $(x_i \perp x_j \mid h)$ and $(h_i \perp h_j \mid x)$ for all $i \neq j$:

$$\begin{aligned}p(h \mid x) &\stackrel{\text{Model}}{=} \prod_{j=1}^N \Pr_j(h_j \mid x) \\ p(h \mid x) &= \frac{p(h, x)}{p(x)} = \frac{\frac{1}{Z} e^{x^\top a} \prod_j e^{h_j w_j^\top x + h_j b_j}}{\frac{1}{Z} e^{x^\top a} \prod_j (e^{w_j^\top x + b_j} + e^{-w_j^\top x - b_j} + 1)} \stackrel{\text{Model}}{=} \frac{\prod_j \Pr_j(h_j, x)}{\prod_j \Pr_j(x)} = \prod_j \Pr_j(h_j \mid x) \\ \implies \Pr_j(h_j \mid x) &= \frac{\Pr_j(h_j, x)}{\Pr_j(x)} = \frac{e^{h_j w_j^\top x + h_j b_j}}{\sum_{h_j} e^{h_j w_j^\top x + h_j b_j}} = \frac{e^{h_j w_j^\top x + h_j b_j}}{e^{w_j^\top x + b_j} + e^{-w_j^\top x - b_j} + 1}\end{aligned}$$

This is kind of a softmax function.

$$\begin{aligned}\Pr_j(h_j = 1 \mid x) &= \frac{e^{w_j^\top x + b_j}}{e^{w_j^\top x + b_j} + e^{-w_j^\top x - b_j} + 1} = \frac{1}{1 + \exp(-2w_j x - 2b_j) + \exp(-w_j x - b_j)} \\ \Pr_j(h_j = -1 \mid x) &= \frac{e^{-w_j^\top x - b_j}}{e^{w_j^\top x + b_j} + e^{-w_j^\top x - b_j} + 1} = \frac{1}{\exp(2w_j x + 2b_j) + 1 + \exp(w_j x + b_j)} \\ \Pr_j(h_j = 0 \mid x) &= \frac{1}{e^{w_j^\top x + b_j} + e^{-w_j^\top x - b_j} + 1} = \frac{1}{\exp(w_j x + b_j) + \exp(-w_j x - b_j) + 1}\end{aligned}$$

$$p(x \mid h) \stackrel{\text{Model}}{=} \prod_{k=1}^d \Pr_k(x_k \mid h)$$

$$p(x \mid h) = \frac{p(x, h)}{p(h)} = \frac{\frac{1}{Z} e^{h^\top b} \prod_k e^{x_k a_k + x_k w_k^\top h}}{\frac{1}{Z} e^{h^\top b} \prod_k (1 + e^{a_k + w_k^\top h})} \stackrel{\text{Model}}{=} \frac{\prod_k \Pr_k(x_k, h)}{\prod_k \Pr_k(h)} = \prod_k \Pr_k(x_k \mid h)$$

$$\Pr(x_k = 1 \mid h) = \frac{e^{a_k + w_k^\top h}}{1 + e^{a_k + w_k^\top h}} = \frac{1}{e^{-a_k - w_k^\top h} + 1} = \text{sigm}(a_k + w_k^\top h)$$

$$\Pr(x_k = 0 \mid h) = \frac{1}{1 + e^{a_k + w_k^\top h}} = \text{sigm}(-a_k - w_k^\top h)$$
